ABSTRACT

In the modern world, the search started for cheap and efficient operating system sources has begun can converted to civilian ends. Internet of things (IoT) is one of the most realistic applications for remote control and remote management using a wide network. In this paper, a control system is designed and built to manage and control traffic lights and street lighting systems, as well as turning on/off generators in a small virtual environment. This was implemented by designing and building a hybrid electronic circuit that combines the closed-circuit control system and the open circuit system. The closed circuit regulates the system according to the desired condition without operator interaction; while the open circuit operates on demand. This type of a hybrid control system demonstrated its high flexibility by controlling devices and its high efficiency compared to the closed circuit and the open circuit system independently. It also helps reduce the number of maintenance guys and energy consumption as well as the cost.

1. INTRODUCTION

The Control systems are usually found in a number of practical applications manage people life, such as refineries robotics, manufacturing plants, chemical, traffic control [1, 2], automated control system [3, 4], power systems, and space applications just to mention a few [5-7]. Resources can employees to successfully realize their tasks and targets, as a way to consolidate their well-being and their ability to do well [8-14]. The aim of any electronic control system is to organize, monitor and process commands, guidance and regulate the behavior of other devices or systems using many types of control systems [15, 16].

A control system is defined as a device or set of devices that manages and controls the behavior of another device or system. According to the viewpoint of some engineers, control systems can be classified into two types [6, 7]: open loop control system and closed loop (feedback) control system.

Open-loop system does not monitor or measure the condition of the output signal. In other words; the output signal is independent to the input signal. The circuit of the open loop system has not sensors to tell if their setpoint has been executed which makes the rectification of disturbances impossible. Open loop system works by simple input signals [16]. Its characteristics are not satisfactory in achieving the desired result of the system and observation so this system is too slow [9, 17].

Common examples for open loop (open source) of electronic circuits such as fan ventilation system, vacuum cleaner, home heating system (without sensor or feedback and control), system of traffic lights, switching and extinguishing street lamps along the way, sprinkler irrigation system. Feedback is not

measured. The spray system can be activated on schedule, although there is no need to operate the system because the rain is already available [18-20]. Figure 1 shown the cycle system of open loop controller.

Figure 1. Cycle system of the open loop controller

Theory of closed-loop control is one of the most dynamic tools developed, was used to stabilize everything from satellite to oven temperature. Closed-loop control now includes a vast literature and countless applications [21, 22]. In closed-loop system the output signal is compared with the desired (input) signal through a feedback loop. According to this comparison, the feedback system makes a certain decision. Do not affected by any external or internal influences such as air conditioning and heating systems, automatic pump to raise water from the ground reservoir to the upper reservoir, autopilot and robots [23].

Closed circuit monitoring system in the computer processes the input signals, then sends signals to the devices under its control, e.g. light emitting diode (LED), relay, etc. to respond correspondingly. For example, in an automatic street lighting system, when the computer senses the light is dim, it will send instructions to the relay then the relay will turn on the street lamp which uses large current [24-27]. A computer control system, sensors are used to collect data and then enter the data to the computer for processing to make a decision. There are many types of sensors such as (mechanical sensors, pneumatic sensors, optical sensors, an electrical and light control system etc.) [28, 29]. Sensor can create electrical signals depending on external change. For example, the light sensitive resistor can be used as a light sensor, because of its resistance and the current it will change with the intensity of light in the environment. Input signals will be processed, and then sends output signals to the components under its control, for example, LED, relay, infra-red passive-red (PIR), and motion detector, etc. to carry out a procedure with, a closed loop system, Figure 2 illustrates this.

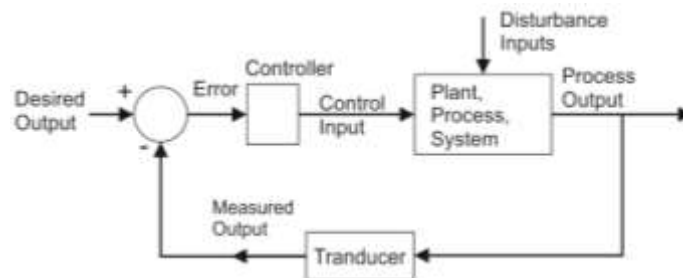

Figure 2. A basic closed loop control system architecture [12]

Durga [30] proposed a closed loop control system for controlling jam traffic. He used IR sensor, encoder and decoder ICs and 8051 micro controllers for measuring the traffic density. Banerjee [6] designed a control system for vehicle management based closed loop system using IC555 timer. Other researchers were designed automatic street light control system uses transistor as switch. They used LDR, PIC161F877A and PIC16F877A microcontrollers in control system [9, 31-35].

The main contribution of this paper establishes an integrated system to operate street lighting, control traffic lights, and operate generators for the virtual city. Two electrical circuits were built. The first is the use of relay systems that control the traffic light operating systems and of the generator. Therefore, two mixed systems were combined, which are the open system and the closed system of electrical circuits, and we called it the system Hybrid. All previous systems used the LDR circuit which was not externally controlled which means a significant consumption of electricity, no matter whether the street's illuminates are needed.

2. RESEARCH METHOD

One of the most important problems in closed-loop circuits are that to provide a measure of control other parts of the circuit, so it must be more complex through in electronic construction, and the problem in open-loop circuit cannot control and measure the parts of an electronic circuit. An alternative system has been proposed to address their problems in the previous two systems, which is called hybrid control closed system as shown in Figure 3. In our proposed system some circumstances the control system requires frequent operator’s intervention to force the system works as desired. In such a case the proposed system needs a high level of decisive action to work correctly and decision (or goal) through monitoring.

Figure 3. A hybrid control closed system

2.1. General diagram of the proposed system

Automata system for modern city consists of two parts; hardware such as: KIT circuit, diode, relay, resistors, transistor, LEDs, LDR, battery, parallel port (8 data pins and Ground pins) and software (which programmed by using V.B 6.0) for monitoring the system on the PC. Computer supplies power of 4.5V via the parallel port. In addition, a transistor BC546 was adding to control the relay due to the minimum amount of ampere. Figure 4 illustrated the general diagram of our proposed system.

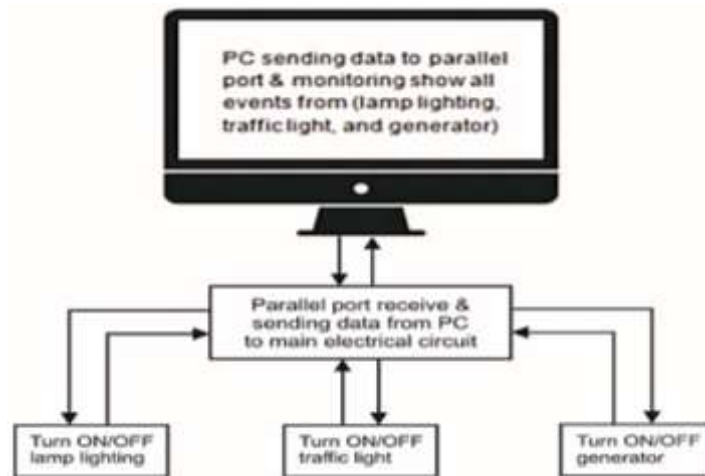

Figure 4. General diagram of the proposed system

2.2. Parallel port and circuit

Parallel port (25 pins) as Figure 5 connected between the computer and the circuit to send instructions as a signal and the circuit distributed the signal to turn on/off the devices. A relay is an electrically activated switch. It depends on internally a coil which will generate a field of a magnetic and attracts a movable lever and then changes switch contacts when a current is flowing through it. The exemplary usage of really switch is to let a low DC voltage in circuit one to turn on or off a high voltage (DC or AC) in circuit two without direct electrical connection between them. This means circuit one and circuit two are magnetically and mechanically linked but not electrically connected. Nine relays 12V were used in this proposed system, eight of them were installed directly in the main circuit and Ninth relay was installed in the LDR circuit as shown in Figure 6.

Figure 5. Parallel port with 25 pin out

Figure 6. Main circuit of the proposed system

2.3. Street lighting with light dependent resistor circuit (LDR)

The light-based resistor (LDR) in this circuit uses a light sensor that LDR resistance will be low if there is light as shown in Figure 7. So the voltage drop across R2. In this case, the transistor BC54 (Q1) will keep ON. The transistor Q1 is connected with transistor BC547 (Q2). So Q2 will be shut down and so do the relay. The lamp will remain OFF. If night falls, the resistance of LDR will be increased to make the voltage difference across the resistor (R2) less than 0.6V. This makes the transistor Q1 turn OFF which in turn makes Q2 ON. The relay will be activated and the lamp will be ON. Adaptation our proposed circuit as shown in Figure 8. We connected with relay in main board in two phases. Figures 7 and 8 illustrate LDR circuit components designed with Proteus V.8 Program.

Figure 7. Traditional diagram LDR circuit

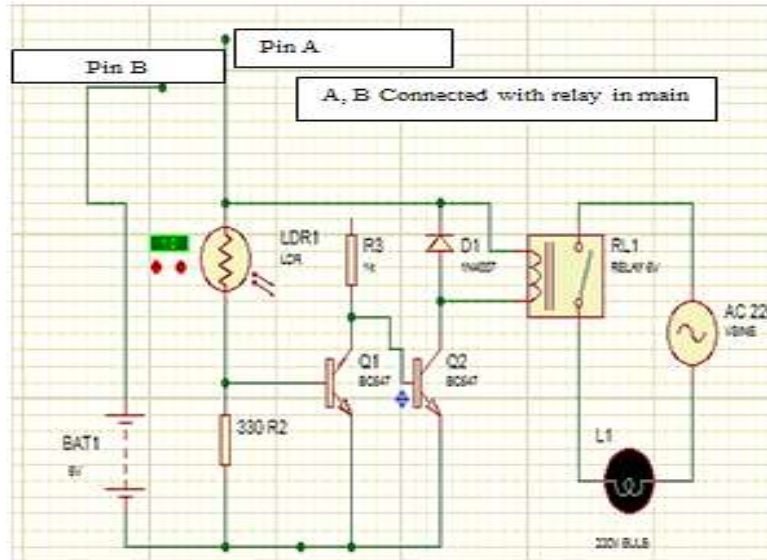

Figure 8. LDR circuit connected with main circuit

2.4. Traffic light streets

In this stage using the timer feature which is provided by the V.B program, has been used to control the relay circuit to activate street traffic lights. If the traffic light (T1) is turn ON for 180 sec., then the other traffic light (T2, T3, T4) will turn OFF thus, for the rest of other cases in succession. The monitoring system (PC) can be controlled to be turned OFF the traffic light when there is no street congestion and school attendance is over. The flowchart in Figure 9 illustrates all the cases of the traffic light.

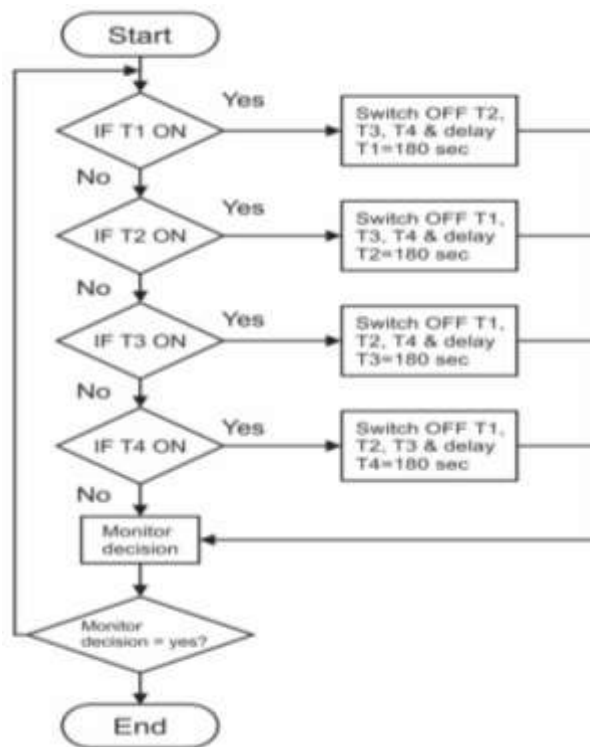

Figure 9. Flowchart shows the work of traffic lights

3. RESULTS AND DISCUSSIONS

In this proposed system, an integrated system was established to operate street lighting, control traffic lights, and operate generators for the virtual city. Two electrical circuits were built. The first is the use of relay systems that control the traffic light operating systems and of the generator. The second section concerns the construction of a dual-functional circuit, which automatically controls the light on the street depending on the external light intensity sensitivity that is using LDR circuit, and also the lighting process is controlled through the computer's system operator by adopting the actual need to turn on the light. Therefore, two mixed systems were combined, which are the open system and the closed system of electrical circuits, and we called it the system Hybrid. All previous systems used the LDR circuit which was not externally controlled which means a significant consumption of electricity, no matter whether the street's illuminates are needed as shown in Figures 10 and 11.

The time length between 03:00 a.m o'clock and the sunrise is longer in the winter so if the dimming is decreased towards to sunrise, energy saving will not be more than before. According to scenario above when lighting control system is operated such as the time length from the sunset to 21:00 a'clock and with 100% performance, between 09:00 p.m and 11:00 p.m o'clock and 80% performance, from 03:00 to the sunrise and 70% performance level, the amount of energy saving is 24.1% during a year.

4. CONCLUSION

Electronic control systems have many benefits such as reducing financial and administrative spending and contributing to the growth of industrial production. In this system, the open and closed systems were combined together because the two systems have defects in speed, performance and results, thus it

called a hybrid control system. This system reduces the power consumption by automating the system, reducing the number of supervising workers and facilitating the maintenance and operation of the system for long periods of time and can be controlled by the computer (on demand) by turning off all the circuits associated with it. Electronic circuits for telecommunication networks can be extended to large cities and long distances, through internet systems to speed up transmission and reception signals and speed decision making.
