Intrusion detection methods Intrusion detection systems Wireless sensor networks WSN WSN attacks WSN security

ABSTRACT

One of the most important aspects of the effective functioning of wireless sensor network (WSN) is their security. Despite significant progress in WSN security, there are still several unresolved issues. Many review studies have been published on the problems of possible attacks on WSN and their identification. However, due to the lack of their systematic analysis, it is not possible to fully substantiate practical recommendations for the effective application of the proposed solutions in the field of WSN security. In particular, the creation of methods that provide a high degree of security while minimizing computational effort and costs, and the development of effective methods for detecting and preventing attacks on WSN. The purpose of this document is to fill this gap. The article presents the results of the study in the form of a systematic analysis of the literature with a targeted selection of sources to identify the most effective methods for detecting and preventing attacks on WSN. By identifying the security of WSN, which has not yet been addressed in research works, the review aims to reduce its impact. As a result, our extended taxonomy is presented, including attack types, datasets, effective WSN attack detection methods, countermeasures, and intrusion detection systems (IDS).

1. INTRODUCTION

Wireless sensor networks (WSNs)are used for many purposes, primarily as the communication backbone of the internet of things (IoT). A sensor network also creates access to the physical world. WSN are networks that embed a large number of sensor nodes in the environment. The use of WSN is increasing significantly day by day [1], [2]. The rapid development of WSN and the IoT is responsible for generating huge amounts of data in various forms that require careful authentication and security. At the same time, there continue to be limitations in the form of security issues and limited performance due to insufficient memory resources or computational power. These circumstances are risk factors that reduce the positive effects of WSN and IoT technologies. In this regard, the challenges of effectively addressing these issues are significantly actualized.

Application areas of WSN include medical, industrial, agricultural, military applications, monitoring systems, transportation tracking, home automation, security and surveillance [3]-[5] as shown in Figure 1. Depending on how sensor nodes are deployed, WSN are categorized into five groups: terrestrial, underground, multimedia, underwater and mobile [6]. However, this diversity of usage poses serious limitations to address specific security and reliability challenges in WSN, which may face a multitude of failure and failure-related problems. The consequences of security breaches and attacks on WSN can be particularly severe in government, military, medical or industrial organizations, where important information can be damaged or stolen [7]. One of the main risks is the possibility of unauthorized access to the WSN system [8]. In addition, WSN can be the target of a denial-of-service (DoS) attack [5]. Attackers can overload the network with a large number of requests or create a botnet to attack the system. This can lead to network resource overload, DoS and disruption of facilities. To protect WSN from such threats, WSN security measures should be implemented. This may include encrypting data transmitted, installing authentication and access control mechanisms, and monitoring the network for anomalies. In addition, regular software updates and training of personnel on WSN security measures are also important aspects [9]. Understanding these risks and applying appropriate security measures are integral to the successful operation of WSN. In this regard, it is relevant to solve the problem of identifying attacks on WSN.

Figure 1. WSN applications

Cybersecurity attacks have increased rapidly in various fields such as building management, healthcare, energy, agriculture, automation and industrial processes [10]. Different techniques and protocols are used to achieve authentication, encryption and data integrity [11]. The application of various techniques to detect WSN attacks is gaining popularity [12]-[14]. The security challenges of WSN include:

- Lack of security standards and uniform data protection principles for WSN can lead to incorrect or incomplete implementation of security measures, and make it difficult to assess the security level of the overall system. Different devices may have different levels of security, and their dynamic nature, such as relocation or addition and removal from the network, can create difficulties in establishing and maintaining data protection. WSN are at risk of cyberattacks due to the deployment of sensor nodes without a defined wireless communication structure and the lack of robust network security protocols.
- Limited computing resources, memory and energy efficiency of sensor nodes do not allow for the implementation of high-performance data processing algorithms and sophisticated analytics, complex data protection and encryption mechanisms. Due to inadequate cybersecurity and the failure to apply appropriate data protection measures both directly in the sensor nodes and in the wireless network infrastructure, there is the potential for cyber threats such as data interception, spoofing, or discrediting, as well as attacks on communication protocols or the network infrastructure. Sensor nodes in WSN are limited by their computational capabilities, memory capacity, battery life, communication range, bandwidth and security. These limitations make them vulnerable to various threats and compromises.

- Intrusion detection problem is very important in the case of WSN. Traditional approaches that analyze
 network anomalies at multiple points of concentration are costly in terms of network memory and power
 consumption. Therefore, there is a need for decentralized intrusion detection.
- Traditional security protocols are not well suited for WSN due to the limited network resources and the isolated, uncontrolled nature of sensor node placement. Different devices may have different levels of security, and their dynamic nature, such as moving or adding and removing them from the network, can create difficulties in establishing and maintaining data protection. WSN may be vulnerable to attacks on the physical parameters of the environment in which they operate.

The current state of research in approaches, methods, techniques and models, algorithms for attack identification and security assessment of WSN is an actively developing field. This paper analyzes recent research and advances with the identification of WSN security gaps. Solutions to these identified gaps are detailed in section 3, and recommendations of security measures are proposed, and recommendations of security measures are proposed for WSN.

The study aims to develop a systematic literature review on WSN insecurity and to identify the most effective methods for detecting attacks on WSN, and to analyze effective methods and tools for preventing such attacks. The main contribution of this research is:

- Performing a systematized literature review to assess the current state of the problem of WSN safety and security in the last 5 years.
- Categorizing the research, according to the types of algorithms used methods of attack identification, IDS and types of threats.
- Analyzing known methods, models, algorithms for identifying attacks on WSN in order to identify their effectiveness.
- Compilation of a comprehensive taxonomy on classifications of attack types, datasets, controllers, recommendations, effective methods for detecting attacks on WSN and on intrusion detection system (IDS) architectures in the context of WSN.

Figure 2 shows how the article is organized, which consists of four sections. The introduction is described in section 1, which includes the main problems and relevance of the study, the purpose and main contribution of the article. Section 2 is devoted to the research methodology, which includes research questions and strategies for finding related work. Section 3 describes the result, which compiles the empirical analysis and proposes our extended WSN security taxonomy and discussion. Finally, section 4 describes the conclusion.

Figure 2. Paper organization

2. RESEARCH METHOD

This section demonstrates the methodology for conducting a systematic review of the article. The focus was on research related to WSN security. This section is composed of the following parts: research questions and hypotheses, search strategy, keywords and paper selection criteria.

2.1. Research questions and hypotheses

These research questions and hypotheses in Table 1 can guide further investigation into the security measures of WSN, contributing to the development of more secure and resilient WSN systems. This paragraph consists of research questions and hypotheses aimed at improving the security of WSNs. Additionally, the study compares various IDS, examines different attack datasets, and reviews vulnerability databases to develop robust security models for WSNs.

	Table 1. Research	i questions and hypotheses
No	Research questions	Hypotheses
1	How effective are machine learning (ML) and deep learning techniques in detecting intrusions in WSN?	ML, deep learning and artificial intelligence techniques significantly improve the accuracy of intrusion detection in WSN compared to traditional methods.
2	What are the comparative advantages and disadvantages of anomaly-based IDS versus signature-based IDS in the context of WSN security?	Anomaly-based IDS are more effective in detecting novel attacks in WSN, whereas signature-based IDS are faster and more efficient in identifying known attacks.
3	How do different attack datasets contribute to the development of more robust security measures in WSN?	Utilizing a combination of different attack datasets for training IDS models leads to a more comprehensive and adaptable security system in WSN.
4	What role do vulnerabilities datasets play in enhancing the security framework of WSN?	Regular updates and integration of vulnerabilities databases into WSN security frameworks significantly reduce the risk of successful cyber-attacks.
5	How can the principles of confidentiality, integrity, and availability be best implemented in WSN to ensure maximum security?	Implementing a multi-layered security approach that addresses confidentiality, integrity, and availability can significantly enhance the overall security of WSN.
6	What are the most significant privacy concerns in WSN, and how can they be addressed effectively?	Addressing privacy concerns such as identification, localization, and profiling through advanced encryption and anonymization techniques can significantly enhance user trust in WSN applications.
7	Which types of attacks on WSN are most prevalent at each layer of the network, and what are the most effective countermeasures?	Layer-specific security measures tailored to the unique vulnerabilities of each network layer are the most effective strategy for mitigating attacks on WSN.

Table 1. Research questions and hypotheses

2.2. Search strategy, keywords

A search strategy was developed for this study to search and identify relevant literature sources. The selected keywords searched include "WSN", "wireless sensor networks", "WSN security", "WSN attacks", "intrusion detection systems", "intrusion detection methods". They were linked using the logical operators "AND", "OR" as shown in Table 2. Relationships in the form of: (TITLE ("WSN") OR TITLE-ABS-KEY ("Wireless Sensor Networks") AND TITLE-ABS-KEY ("WSN security") OR TITLE-ABS-KEY ("Wireless Sensor Networks security") AND TITLE-ABS-KEY ("attack") OR TITLE-ABS-KEY ("cyberattacks") OR TITLE-ABS-KEY ("Intrusion Detection Systems") OR TITLE-ABS-KEY ("Intrusion Detection Systems") OR TITLE-ABS-KEY ("Intrusion Detection Methods")).

SCOPUS, Google scholar, Crossref, Semantic scholar databases are selected for this research study using the study of the last five years from 2019-2023 as shown in Table 3. Scientific databases from the sources listed above, are summarized in Table 3, and keywords are summarized in Table 2. Specific search strategies were also used. In particular, research articles were analyzed for inclusion and exclusion criteria as shown in Figure 3.

The criterion for selecting articles for further review and analysis was defined, i.e., the method of searching and selecting articles using specialized keys and PRISMA meta-analysis [15], [16], as shown in Figure 3. The PRISMA flowchart, describes the process of identifying studies in scientific databases for systematic review. The flowchart is divided into four main steps: identification, screening, selection and inclusion. The algorithm results in the selection of 100 articles according to given requirements for further research.

Figure 3. PRISMA flow diagram on selection and screening of the papers

2.3. Paper selection criteria

The selection criterion was based on the PRISMA flow diagram. The search first focused on existing research on WSN attack detection methods and algorithms, WSN security, and WSN attack detection methods. The search covered the period from 2019 to 2023. First, all articles published before 2019 were excluded from the search. Then, all articles written in languages other than English were excluded. The search was mainly focused on matching research on the defense of wireless sensor networks. In order to identify studies through scientific databases using PRISMA scheme, first, 1,038 articles from different database from Table 3 were effectively collected and imported. After importing the collected studies, a screening process follows. In the screening process, firstly, duplicates are removed and then 230 articles are selected for further screening. Articles in the field of computer science, engineering were selected. The duplicate 44 articles were eliminated. Next, articles with high h index were selected. After screening, another 20 articles from own database were added to the study list. Screening result of included and excluded articles is shown in Figure 4. After that, 100 articles were selected and included as shown in Figure 4(a) for further analysis of papers. 130 articles were excluded as shown in Figure 4(b). Table 4 shows the inclusion and exclusion criteria for research articles.

Figure 4. Screening result of (a) included and (b) excluded articles

Parameters	Exclusion	
Source	Published works in different journals or conferences	-
Year of publication	2019-2023	to 2019
Language	English	Other languages
Field of science	Computer science, engineering	Other fields
Citation and Index	More citations	Less citation
	High h index	Without h index
Duplication	-	Duplicates
Own database	+ 20 databases	-

Table 4. Criteria for inclusion and exclusion of research articles

The study involved extensive data collection, which was stored in a spreadsheet with the addition of an in-house database. This data included information on the title of the articles, authors, year of publication, dataset, IDS, algorithm or method used, model performance, types of attacks on WSN, annotations, and data sources. This approach allowed us to organize and organize the information, which further facilitated the work. Several interesting findings emerged from this study. First, it was found that the use of different types of artificial intelligence algorithms can significantly affect the performance of models.

2.4. Quality assessment

Articles, review articles and conference proceedings were used in the quality assessment process of this review. To ensure the quality of the review, all repeated entries were carefully checked. Each study was carefully evaluated. Article abstracts were screened in depth to analyze and clean the articles to ensure the quality and relevance of the research article included in the review process.

The study selection criteria showed high relevance and reliability of information. It is important to note that this assessment is a result of the analysis, thus giving credence to the findings and recommendations. This review is a reliable and relevant source of information on the topic.

Our study emphasized the need for an extended study of this topic. The findings suggest that the complexities inherent in this topic are far-reaching and require more in-depth study. We can hope to show the intricacies of the field, thereby contributing to a more complete understanding that can potentially inform future academic discussions and practical applications. It is important to note that this assessment results from an analysis, which allows you to trust the conclusions and recommendations obtained. This review provides a reliable and up-to-date source of information on the topic.

3. RESULTS

This section presents a comprehensive analytical review and empirical analysis of WSN security, covering classifications by attack type, IDSs, attack identification techniques, algorithms, models, and existing security taxonomies. The proposed extended taxonomy of WSN security measures reflects the evolving landscape of cybersecurity threats and defense mechanisms, offering a forward-looking perspective on WSN security, covering classifications based on attack types, IDSs, attack identification methods, algorithms, models, and existing security taxonomies. The proposed extended taxonomy of WSN security measures reflects the evolving landscape of cybersecurity taxonomies. The proposed extended taxonomy of WSN security methods, algorithms, models, and existing security taxonomies. The proposed extended taxonomy of WSN security measures reflects the evolving landscape of cybersecurity threats and defense mechanisms, offering a forward-looking perspective on security measures reflects the evolving landscape of cybersecurity threats and defense mechanisms, offering a forward-looking perspective on securing wireless sensor networks.

3.1. Analysis of selected articles by publisher and by year

Figure 5 shows the structured number of articles that were selected for analysis from those published by reputed scientific publishers between 2019 and 2023. Including 'IEEE Xplore' with 17.9%, 'Springer' with 20.2%, sources include 'Elsevier' with 13.1%, 'Other' with 10.7% and 'Academia.edu' with 6.0%. Smaller segments are represented by sources such as 'Wiley Online Library' with 4.8%, 'Taylor and Francis' with 2.1%, 'ACM' with 2.4%, 'Science Direct' and 'Scholar.archive.org' with 2.4%, 'ResearchGate' with 7.1%, 'MDPI' with 6.0%, and 'IJETT' with 1.2%.

Figure 5 provides a visualization of the variety of sources used to access research papers and shows that there is a range of preferred sources on the research topic within the research community. Figure 6 shows the annual distribution of research from 2019 to 2023. It has been observed that the number of studies has not decreased over the years, which means that the areas of attack identification and security assessment of WSN are gaining popularity and attracting more attention from various scholars as the security of WSN is relevant.

Figure 5. Articles selected for review publisher

Figure 6. Distribution of studies by year of publication

3.2. Classification of studies on types of WSN attacks

Attacks on WSN can be classified based on their purpose, type and methods used. By purpose, attacks can target data availability, integrity or confidentiality. By type, attacks can be passive or active. Passive attacks involve intercepting and analyzing traffic, while active attacks involve altering or destroying data [17]. According to the methods used, attacks can be based on physical vulnerabilities, software vulnerabilities or protocol vulnerabilities.

When WSN are used in different domains, a variety of attack scenarios are possible. The articles [18] classify attacks into 6 main categories: physical attacks, network attacks, software attacks, encryption attacks, data privacy attacks, encryption attacks. And common attacks on wireless sensor networks include:

- Network availability attacks, such as DoS attacks, which can overload a network and make it unavailable to legitimate users [19].
- Data integrity attacks, such as message spoofing attacks, which can alter or delete data on the network [20].
- Data privacy attacks, such as traffic hijacking attacks, which could lead to the disclosure of sensitive data [21].
- Software attacks, such as buffer overflow attacks, which can lead to the execution of arbitrary code on the network.
- Protocol attacks such as routing attacks that can lead to network disruption or traffic redirection.

The classification of WSN attacks is presented in Figure 7 and the types of attacks and defense techniques are described in Table 5.

Figure 7 presents the different types of network attacks, which can be useful for analyzing cybersecurity and prioritizing defense strategies. Attacks involving the software layer are among the most common. This type of attacks can exploit vulnerabilities in WSN software to gain control over the network [32]. To protect WSN from attacks, various security measures such as: i) data encryption: encryption protects the data from unauthorized access; ii) authentication and authorization: authentication and authorization make sure that only authorized users can access the network and its resources; and iii) attack detection and response: attack detection and response systems can help detect and remediate attacks in real time. Following these security measures can help protect the WSN from attacks and ensure safe and secure network operations. Figure 8 illustrates the variety of attacks that can occur in WSN and the different strategies used to control measures WSN from these threats.

Figure 8. WSN attacks and countermeasures

3.3. Classification of IDS-based studies

The section is dedicated on the classification of research on IDS-based WSN IDS. An IDS sometimes known as an intrusion prevention system (IPS) is an active defense mechanism deployed by the IoT that can recognize intrusion activity and initiate alerts [33]. However, as the number of hazards increases, questions arise about the long-term viability and practicality of current methods. These considerations are particularly relevant in light of the increasing level of adaptive performance and the lack of detection accuracy. Intrusion detection capabilities include: monitoring and analyzing user and system activities; analyzing system configuration and vulnerabilities; assessing system and file integrity; the ability to identify attack patterns; analyzing anomalous activity patterns; and tracking users for policy violations [34].

Research analysis has shown that there are four main methods to build an IDS: signature-based and data-based, behavior analysis-based IDS, and artificial intelligence-based IDS. Each type of IDS has its own advantages and disadvantages [35]. The selection of the most appropriate system depends on the specific requirements of a particular organization. In some cases, it may be necessary to deploy multiple IDS types to ensure comprehensive coverage [36]. Table 6 shows the classification of selected studies on IDS, detection categories and detection methods, attacks and threats [37]. According to the selected studies, most of the researchers used WSN based IDS, distribution-based IDS, anomaly-based IDS, DL based IDS, and ML based IDS and that the proposed IDS improves security, detection accuracy.

Existing IDSs for WSN have several shortcomings. First, they often do not take into account the specific characteristics of WSN, such as limited computational resources and low bandwidth. Second, they are often unable to detect sophisticated attacks that can be disguised as legitimate traffic. Figure 9 shows that the application efficiency is more in WSN-based IDSs, ML-based IDSs, and DL-based IDSs. The literature review of IDS for WSN identified the following problems that need to be addressed:

- Lack of attention to privacy. Most existing IDSs do not consider privacy issues that may arise when using WSN.
- Lack of comprehensive approach. Most existing IDSs focus on detecting attacks on one layer of WSN while ignoring attacks on other layers. This leads to the fact that IDSs cannot provide a complete defense of WSN against all possible attacks.
- Insufficient research on some types of attacks. Some types of attacks, such as attacks on the physical layer of WSN, are not sufficiently studied. This makes it difficult to develop effective methods to defend against such attacks.

It is necessary to develop new IDSs that will take into account the specific characteristics of WSN, provide a comprehensive approach to attack detection and will be able to detect complex attacks.

3.4. Classification of studies based on attack identification methods, algorithms and models

This section describes studies based on attack identification methods and algorithms. Some studies [66]-[75] use data-driven approach because signature-based methods cannot detect zero-day attack. To identify WSN attacks, several data-driven approaches based on ML or DL methods have been proposed in the articles. The fundamental limitations of these approaches include the use of raw features to build an intrusion detection model, which may result in low detection accuracy. There are studies that implement entity embedding for the sake of transforming raw features, to provide accurate detection. Table 7 in Appendix shows the studies classified based on attack identification methods and algorithms.

Figure 10 shows the categorization of studies on attack detection methods, algorithms, and technologies that have investigated the implementation of various AI algorithms. These algorithms include XGBoost, extreme learning machine (ELM) algorithm, Naive Bayes (NB), decision tree (DT), random forest (RF), support vector machine (SVM), probability support vector machine (LSVM), long short term memory (LSTM), recurrent neural network (RNN), convolutional neural network (CNN) deep neural network (DNN), K-nearest neighbors (K-NN) algorithm, fuzzy pattern tree (FPT), fuzzy logic algorithm, C-means, logistic regression (LR), deep learning (DL), and artificial neural network (ANN), CNN+RNN. The results of the analysis show that most of the studies utilized DL algorithms and various ML algorithms, while other studies focused on current issues related to WSN and IoT security.

Figure 10. Classification of research by methods, algorithms and technologies for detecting attacks

3.5. Taxonomy classification of studies

This section presents the taxonomy of security attacks, different IDS mechanisms to detect the attacks and performance metrics used to evaluate the IDS algorithm for WSN. The taxonomy of security threats for each layer and different algorithmic solutions that have been studied by numerous researchers aim to counter this attack and will allow more accurate reflection of network threats in new datasets. According to the presented taxonomies of modern IDSs, a comprehensive review of recent works, it can be concluded that WSN are becoming more secure. Table 8 and Figure 10 summarize the studies classified by taxonomy.

Indonesian J Elec Eng & Comp Sci, Vol. 36, No. 1, October 2024: 318-337

From Table 8, we can summarize that improving anomaly detection techniques is of great importance in combating cyberattacks. It can identify typical attacks and detect potential threats at early stages, which helps to better protect information systems and reduce risks and for better performance evaluation [115], [116]. ML and DL are becoming more and more widely used in the field of WSN and IoT security. This is due to its ability to analyze large amounts of data and detect anomalies in the performance of systems. ML algorithms learn from the data provided to them and can predict possible vulnerabilities and attacks. Thus, they can be an effective tool in combating cyber threats related to WSN and IoT [117], [118]. All these aspects are widely discussed in academia and practitioners to develop more reliable and secure WSN and IoT systems. However, it is necessary to continuously develop technical tools and strategies to maximize the effectiveness and protection against possible cyber threats in WSN and IoT.

3.6. Result of the taxonomy of security measures in WSN and discussion

Thus, our extended taxonomy of security measures in WSN is proposed based on the results of the study. This taxonomy can be characterized as containing elements of a systematic approach to analyzing and addressing WSN security issues. Our extended taxonomy is presented in Figure 11, which includes attack types, datasets, effective methods for detecting attacks on WSN, countermeasures, and IDS. In addition, the presented taxonomy exhausts the gaps in building an IDS in WSN, and the shortcomings of the approaches proposed by researchers are identified. The detailed taxonomy of security measures in WSN aligns well with the initial hypotheses, providing a comprehensive framework that supports the effectiveness of ML, DL, and AI, the importance of IDS types, the role of attack and vulnerabilities databases, the implementation of security principles, the need to address privacy concerns, and the efficacy of layer-specific security measures. This comparison highlights the depth and relevance of the taxonomy in guiding research and development efforts in securing WSN.

Figure 12 illustrates future WSN security research directions and their relative importance based on a hypothetical assessment. These areas include advanced encryption techniques, AI and ML for threat detection, energy-efficient security protocols, blockchain applications, and more. Each area is critical to improving the security and efficiency of WSN. Future WSN security research directions can make a meaningful contribution to the development of more secure, efficient, and resilient WSN that can meet the cybersecurity challenges of the future.

Security in WSN and IoT is a challenging task not only due to the limited resources of end devices along with link losses but also due to new communication and networking technologies. Analyzing recent research studies on different types of attacks shows varying levels of attention and study. Some attacks attract significant research interest while others are relatively ignored. Researchers need to focus on understanding and mitigating all forms of attacks to improve network performance and security in the future.

Currently, many strategies only consider specific types of attacks on individual layers of WSN, ignoring attacks on other layers. However, there is a need to develop a cross-layer IDS capable of detecting multiple attacks at different layers of WSN. In conclusion, securing WSN is a multifaceted task that requires an integrated approach. The proposed recommendations and our taxonomy together form a sound framework for enhancing WSN security. By applying these measures in real-world applications, WSN can significantly reduce the risks associated with cyber threats, unauthorized access, and data leakage in the WSN environment.

Figure 11. Taxonomy of WSN security

Figure 12. Future research directions

4. CONCLUSION

In this paper, we performed an analytical review of WSN security article selected using specialized procedures to highlight the most informative and relevant scientific publications. As a result, we found a lack of comprehensive reviews on WSN. Existing reviews either provide minimal information on attacks or focus on network security and its impact on energy dissipation. To address this gap, we propose a new taxonomy to categorize WSN security measures.

Based on the results of this study, we performed a systematic literature review to assess the current state of the WSN security and protection problem in the last 5 years. We categorized the research, according to the types of algorithms and methods used to identify attacks, and types of threats and the results of the classification revealed that the improvement of anomaly detection methods is of great importance in the fight against cyberattacks. We analyzed the IDS identification of attacks on WSN to identify their effectiveness. Furthermore, Research on ML, DL, and AI techniques for effective detection of different types of attacks, which are key actions in combating cyberattacks and securing WSN and IoT, is categorized. Lastly, a taxonomy of WSN security measures is proposed, based on analytical and empirical analysis.

To successfully deploy and operate fault-tolerant and fault-tolerant WSN, several challenges related to their reliability, energy efficiency, management and security need to be addressed. Implementing modern authentication and authorization mechanisms, using data encryption, monitoring and detecting incidents, and regular security testing, creating standards and using new technologies such as blockchain, creating a security culture can significantly improve the security of WSN and ensure their safe and secure operation. Further research and development in this area is essential to ensure the resilience and security of WSN. Further work is also needed to improve the accuracy of attack detection with real applications and on real datasets to detect new types of threats.

BIOGRAPHIES OF AUTHORS

Tamara Zhukabayeva ^[D] **[S]** ^[C] is currently an Associate Professor in informatics, computer engineering and management with L. N. Gumilyov Eurasian National University, Astana, Kazakhstan. She is also an Associate Member of the Universal Association of Computer and Electronics Engineers and has membership in scientific societies in the society of digital information and wireless communications (SDIWC) and the Universal Association of Computer and Electronics Engineers. She has published over 70 scientific and educational-methodical works: in the Republic of Kazakhstan and countries far and near abroad, including a foreign edition from the clarivate analytics database, Scopus. She is the author and co-author of educational publications and scientific monographs and has innovative patent and copyright certificates for intellectual property rights. She can be contacted at email: tamara_kokenovna@mail.ru.

Lazzat Zholshiyeva **(D)** S **(S) (C)** in 2003, she graduated from the Taraz State University named after M. Kh. Dulati with a degree in mathematics and computer sciences. In 2012, she received a Master's degree in mechanical engineering. In 2020, she graduated from the doctoral program "Astana International University", specialty 8D06101- "Computing and software". Her research interests include computer vision, machine learning, IoT. Researcher at the international science complex "Astana". She can be contacted at email: lazzat.zhol.81@gmai.com.

Khu Ven-Tsen D S S C is Doctor of Technical Sciences, Professor, Higher School of Information Technologies and Energy, M. Auezov South Kazakhstan State University, Shymkent, Kazakhstan. Scientific direction - Automation of technological processes and production, automated optimal control of complex technological systems. He can be contacted at email: qbcba@bk.ru.

D 337

Yerik Mardenov (i) S (c) graduate of OP 6D070400 Computer technologies and software, Eurasian National University named after L. N. Gumilyov. The topic of the dissertation is "Development and research of algorithms and models for analyzing the security of software and hardware components of wireless sensor networks". Director of the Information Technology Department at Astana International University. He can be contacted at email: emardenov@gmail.com.

Aigul Adamova (D) (S) (C) received the Ph.D. degree in computing and software from L. N. Gumilyov Eurasian National University, Kazakhstan, in 2016. She is currently the Head of the Career and Employment Center, Astana IT University. She has about 40 published papers in refereed journals and conferences. Her teaching interests include operation systems, algorithms, embedded systems, programming languages, cybersecurity, computer vision, information security, and mobile robotics. She can be contacted at email: aigul.adamova@astanait.edu.kz.

Nurdaulet Karabayev b s s b master's student at Astana IT University, junior researcher at the International Science Complex "Astana". He has published more than 5 scientific and educational works: in the Republic of Kazakhstan, countries far and near abroad. He can be contacted at email: 222240@astanait.edu.kz.

Assel Abdildayeva **b** S **s c** received her Ph.D. International University of Information Technologies, Kazakhstan. Currently, she is an associate professor at the Department of Artificial Intelligence and Big Data, KazNU named after. Al-Farabi, Almaty, Kazakhstan. She has published more than 40 scientific and educational works: in the Republic of Kazakhstan, countries far and near abroad. She can be contacted at email: abass_81@mail.ru.

Dilaram Baumuratova b B s c Ph.D., senior lecturer at the Pedagogical Institute of Astana International University. She has published more than 20 scientific and educational works: in the Republic of Kazakhstan, countries far and near abroad. She can be contacted at email: Baumuratova.d@gmail.com.
